*% detected as AI

AI detection includes the possibility of false positives. Although some text in this submission is likely AI generated, scores below the 20% threshold are not surfaced because they have a higher likelihood of false positives.

Caution: Review required.

It is essential to understand the limitations of AI detection before making decisions about a student's work. We encourage you to learn more about Turnitin's AI detection capabilities before using the tool.

Disclaimer
Our AI writing assessment is designed to help educators identify text that might be prepared by a generative AI tool. Our AI writing assessment may not always be accurate (i.e., our AI models may produce either false positive results or false negative results), so it should not be used as the sole basis for adverse actions against a student. It takes further scrutiny and human judgment in conjunction with an organization's application of its specific academic policies to determine whether any academic misconduct has occurred.

Frequently Asked Questions

How should I interpret Turnitin's AI writing percentage and false positives?
The percentage shown in the AI writing report is the amount of qualifying text within the submission that Turnitin's AI writing detection model determines was either likely AI-generated text from a large-language model or likely AI-generated text that was likely revised using an AI paraphrase tool or word spinner.

False positives (incorrectly flagging human-written text as AI-generated) are a possibility in AI models.

AI detection scores under 20%, which we do not surface in new reports, have a higher likelihood of false positives. To reduce the likelihood of misinterpretation, no score or highlights are attributed and are indicated with an asterisk in the report (*%).

The AI writing percentage should not be the sole basis to determine whether misconduct has occurred. The reviewer/instructor should use the percentage as a means to start a formative conversation with their student and/or use it to examine the submitted assignment in accordance with their school's policies.

What does 'qualifying text' mean?
Our model only processes qualifying text in the form of long-form writing. Long-form writing means individual sentences contained in paragraphs that make up a longer piece of written work, such as an essay, a dissertation, or an article, etc. Qualifying text that has been determined to be likely AI-generated will be highlighted in cyan in the submission, and likely AI-generated and then likely AI-paraphrased will be highlighted purple.

Non-qualifying text, such as bullet points, annotated bibliographies, etc., will not be processed and can create disparity between the submission highlights and the percentage shown.

JourneyBox: A Smart Mobile Travel Companion for Trip Information Management and Assistance

Abstract - Customers often find it hard to deal with the trip information like itineraries, booking confirmations, travel documents, costs, and emergency information. All of this data can easily be distributed in emails, messaging applications, screen shots and various apps that can be hard to access when traveling, particularly in low-network areas. The paper is a report on a smart travel companion application named JourneyBox, which aims to capture, manage, and support trip-related information using an integrated mobile application. The system offers itinerary planning, document storage, expense, offline, real-time reminders and emergency support features. The application is built based on Android Studio and written in Java, and has a cloud-based backend to facilitate travel management, ensure greater safety, and make it easier to use. The scalable architecture will guarantee the addition of intelligent features like OCR-powered ticket scanning and AI-powered traveling insights.

Index Terms Travel management, mobile application, itinerary planning, offline access, expense tracking, smart travel assistant. assistant.

INTRODUCTION

I. Background and Motivation

The mushrooming of tourism and personal travelling has increased the reliance on online channels to plan and organize travel. Customers depend on their emails, applications, maps, and notes to get their tickets, make their bookings, navigate their locations, and plan their trips. The problem with that, however, is that the lack of unified system leads to a system of fragmented information, confusion and inefficiencies in the process of travelling.

Most tourists encounter the problems of:

1. Inability to access the booking information fast.
2. Late of absence of planned activities or check-in time.
3. Lack of organized trip plans
4. Poor expense tracking
5. Unavailability of information in distant or low network coverage zones.
6. These issues underscore the importance of having a single mobile platform that would be able to capture and handle all the information associated with a trip and help users in the process of their trip.

II. Problem Statement

The current travel applications are oriented to particular services, including the booking of tickets, hotels, or navigation. They do not however offer a centralized system of control of complete trip information. Tourists have to alternate between applications and arrange screenshots or documents manually.

It is evident that there is a need to have a mobile travel assistant application which:

1. Records all trip related data in a central point.
2. Offers systematic itinerary planning.
3. Even works without or with low internet connectivity.
4. Notifications of offers and urgent assistance.
5. Helps track travel expenses stimulation.

III. Proposed Solution

The proposed project is an app JourneyBox a smart travelling companion, which in this case is based on mobile technology, providing planning, storage, tracking, and assistance all in one platform.

The system enables users to:

1. Create and manage trips
2. Plan day-wise itineraries
3. Stock tickets and travel documents.
4. Track expenses and budgets
5. Access information offline
6. Get notifications and warnings.
7. Emergency safety features should be utilized.

IV. Research Objectives

The system has the following objectives:

1. To create a mobile application to manage trip information in an easy- to-use format.
2. To consolidate itinerary, booking and document storage.
3. To offer offline services to access important travel information.
4. To incorporate financial management tracking of the budget when travelling.
5. To improve the safety of the travellers with the help of emergency features.
6. To develop a scalable design of intelligent travel services in the future.

LITERATURE REVIEW

The mobile and travel technology is still redefining how individuals plan, navigate and manage trips. The disjointed ecosystem of travel-related technology in the form of navigation, booking, notes, and expense apps that do not always work with each other was reported early enough to create an apparent opportunity of unified travel assistants [Dickinson et al., 2014]. This trend can be verified by recent systematic reviews and empirical research on smart tourism and the focus on personalization, contextual support, and traveller satisfaction via integrated ICT solutions is growing. In a 2024-2025 systematic review and SLRs, it is noted that the area of smart tourism is maturing and identifies personalization, destination-level services, and satisfaction measures as key areas of concern to new travel systems.

The theme of work is dedicated to mobile travel applications (2020-2024) to study drivers and barriers to adoption and emphasize the importance of perceived usefulness, ease-of-use, and offline reliability as key drivers of adoption. These experiments demonstrate that convenient and trustworthy offline behaviour is a boon to further use - a direct reason why JourneyBox has offline-first and lightweight capture capabilities.

Travel systems are still dominated by location-based services and itinerary support as key technical building blocks. Mapping APIs, geofencing, and POI discovery is shown to generate immediate user value (local discovery, routing, nearby-services look-up), and several implementations and case studies (2015-2024) illustrate this. Recent studies reinforce the notion that on-trip support with the combination of mapping and trip planning, plus the incorporation of contextual triggers (e.g., location-based reminders) is much better.

Mobile applications Document capture and OCR reached maturity quickly (2021-2024). ML toolkits on mobile phones (most notably Google ML Kit Text Recognition v2) can now perform powerful text recognition of a variety of scripts, and are optimized to work on-device, and automatic OCR of PNRs, dates and amounts of tickets and receipts is becoming a viable feature in travel applications as a way of eliminating manual typing. This promotion is a direct benefit to the proposed smart capture module by JourneyBox.

The offline-first pattern has emerged as a significant engineering trend used in travel and other mobility apps (2023-2025). Multiple recent articles and manuals on architectural patterns of offline-first mobile apps, synchronization, and secure local storage cover the advice; the guidelines prioritize the use of local caches, background synchronization, conflict resolution and

eventual consistency - best practices that JourneyBox ought to follow to be resilient on low-network conditions.

The feature of expense tracking and shared-trip finance has received a new wave of interest (2023-2025) with multiple pieces of academic and applied literature explaining mobile expense trackers and behavioural advantages of routinely registering the expense. These demonstrate that straightforward categorical tracking, receipt attachments, and group expense-splitting UX designs enhance adoption by the user and offer valuable analytics on post trip insights. Including such a module into JourneyBox will become a value of the user that should be measured.

Gaps & Research Opportunity. The recent literature and product reviews suggest that although there are numerous applications that can address individual tasks involved in traveling (booking, navigation, note-taking), there are few mobile-first applications that are based on offline-first principles, which capture (OCR) data and can organize it into trip-based vaults, operate offline, track expenses, and provide emergency support in a single lightweight native application. JourneyBox seeks to fill this gap by adhering to offline-first principles, using on-device OCR to capture data, and providing practical safety and finance features with the architecture being modular.

METHODOLOGY AND SYSTEM ARCHITECTURE

I. Development Approach

The system will be based on a modular mobile application development approach, where there is flexibility and scalability. Modules are developed individually and are tested and then integrated to easily develop and maintain.

II. System Overview

The JourneyBox will be made up of the following main modules:

1. Trip Management Module- it is the creation and organization of trips.
2. Itinerary Planner Module- day-wise scheduling.
3. Document Vault Module- tickets and travel files storage.
4. Expense Tracker Module- monitoring expenses and budget.
5. Reminder and Notification Module- schedule notifications.
6. Offline Access Module- offline storage of vital information.
7. Emergency Support Module -SOS and local help.

III. Architecture Layers

The JourneyBox system is based on the layered architecture model that guarantees modularity, scalability and simplicity in maintenance. There is a defined responsibility of each layer, and the interface of each layer is communicated with the neighbouring layers.

1. Presentation Layer: This is an API layer that shows the front-end mobile application written in Android Studio in Java and XML layouts. It deals with all user communications, such as creation of trips, input of itineraries, uploading documents, entering expenses, and taking of emergency measures. The interface is based on Material Design principles, which makes it usable and easy to access. Notifications, reminders, maps, and the travel details that are stored in the backend services are also presented in this layer.

2. Application Layer (Business Logic Layer): Core logic of the system is available in the application layer. It interprets user input and handles processes of trips, costs and schedule management, and regulate the flow of data between the interface and the database. This layer takes care of the validation of trip details, classification of expenses, sending notifications, and data preparation to be sent offline. It is also in charge of communication with outside APIs like Google Maps and notification service.

3. Table Layer (Cloud & Local Table Layer): This layer is in charge of storing and retrieving data. User profiles, trip data, itineraries and expense data are stored in a cloud database (Firebase Firestore or MongoDB). Secure storage of travel documents such as tickets and ID proofs is done through cloud storage. Furthermore, a local storage system installed on the mobile phone stores necessary trip information, which allows one to access it when offline in case there is no internet connectivity.

4. External Services Layer (Integration Layer): The integration layer is used to integrate the application and the third-party services and APIs. It is comprised of Google Maps API to navigate and find places nearby, push notifications to reminders, and optional OCR features to extract automatic ticket data. This layer

guarantees the compatibility between the external services and the app and secure exchange of data.

5. Cross-Cutting Layer (Security Layer) The security layer works on all the other layers in order to guarantee safe processing of user data. It has user authentication, secure API communication, location and storage access permissions as well as encrypted data transmission. This layer enjoys security of sensitive travel documents and personal information stored in the application.

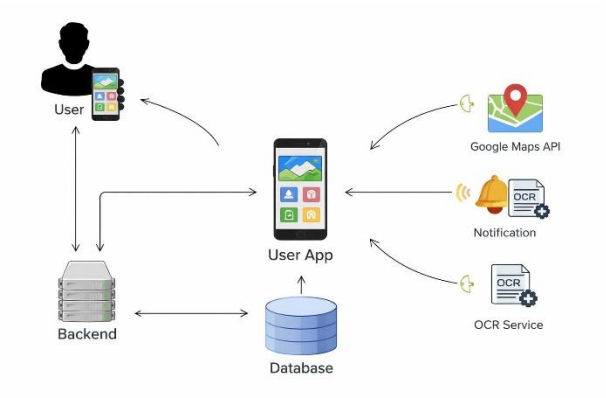

FIGURE 1: Architecture

IV. Workflow

The working process of the system is as follows:

1. User creates a new trip
2. Attaches itinerary, bookings and documents.
3. Incurs investments in transportation.
4. Receives notifications on activities and reservations.
5. Loses information online when they need.
6. Applies emergency equipment in emergency cases.

V. Tools and Technologies Used

Component	Technology Used
Mobile Development	Android Studio
Programming Language	Java
Cloud Database	Firebase
APIs	Google Maps API
User Interface Design	XML
Notifications	Firebase Cloud Messaging (FCM)
Authentication	Firebase Authentication
Version Control	Git & GitHub

IMPLEMENTATION AND MODULE DESCRIPTION

I. System Implementation

The JourneyBox is deployed as a native Android mobile app that is written in Java on Android Studio. The application is designed in a modular manner in order to guarantee maintenance and scalability. The frontend is developed based on XML layouts and the principles of the Material Design in order to offer a simple and clear user interface.

A cloud-based database (Firebase/MongoDB) is used to support the backend services to store user trip data, itineraries, expenses, and document metadata. The cloud storage is utilized to save files related to travels such as tickets and identification documents. It will have location-based services through Google Maps API and push notification services that send reminders and alerts.

The system provides a secure access by using user authentication methods and allows offline storage of important traveling information by caching the device with local storage.

II. Module Description

1. The User Registration and the Login Module: This module enables users to make accounts safely and log in. User information is authenticated and individual trip information is loaded, when a user logs in. It also allows managing the profiles and accessing the stored information about travels safely.
2. Trip Management Module: Users are able to add, modify and delete trips. The trips are filled with information on the destination, the time of travel and notes. This module serves as the coordinator of the information pertaining to the trip.
3. Itinerary Planner Module This module allows a user to organize activities per day. Visitors are allowed to add places, time agenda, and notes per day. The itinerary assists the users in having a systematic plan in their trip.
4. Travel Document Vault They are able to upload and store valuable travel information including tickets, hotel bookings, boarding tickets as well as ID documents. The files are stored safely in

the cloud and can be downloaded to get access to the file offline.

5. Expense Tracker Module: This module assists users to keep track of their daily costs in different categories like, food, transport, accommodation, and shopping. It also determines the total amount of spending and a comparison is made with the intended budget to enable the user manage his finances well.
6. Reminder and Notification Module: Notice boards on various events of importance during a travel like departure time and check in and planned activities are created automatically. Push notifications remind users not to forget about significant events of a trip.
7. Offline Access Module Some of the critical trip data which includes itinerary and downloaded documents are kept on the computer. This will make sure that the users are able to access the necessary information even when there is poor or no connectivity of the internet.
8. Emergency Support Module: The module will be offering quick access to emergency contacts and local essentials in the form of hospitals and police stations via location services. There is an SOS button that lets a user easily find assistance in case of an emergency.

RESULTS AND DISCUSSION

I. System Evaluation

Testing of the system was done using the functional testing, usability testing as well as testing on a per-module basis. All features, including trip creation, itinerary management, document upload, expense tracking and reminders, were individually and combined tested.

Testing showed that:

1. There is accurate storage and retrieval of trip data.
2. It works with offline access to itinerary and documents.
3. Notifications about reminders are sent on time.
4. Calculations on expenses are properly aggregated.
5. The user interface was identified to be user friendly and the modular design enables easy navigation through various features.

II. Discussion

The majority of the travel applications available are concerned with booking services or navigation. JourneyBox is different because it provides the complete travel information management system. It also incorporates planning, storage, tracking, and support in a single platform.

The addition of offline viewing is very advantageous in the case of remote travelling. The cost tracking option incorporates financial management functionality, something usual in traditional travelling applications. The system is further enhanced by safety facilities which cover the security of the travellers.

Though the user testing has not been done on a large scale yet, the modules implemented have a great potential of streamlining and making traveling convenient.

FUTURE WORK

The existing application of JourneyBox gives a solid base of mobile-based travel information management. Nevertheless, there are some additions that can still make the system more intelligent, user-friendly, and scaled. The future work can be dedicated to the following aspects:

1. Intelligent Document Capture based on OCR: The next generation of the system has the ability to incorporate the Optical Character Recognition (OCR) technology that is used to automatically identify important information like travel dates, booking IDs, departure times, and ticket numbers when uploaded travel documents are used. This will lessen the use of manual data entry, enhance accuracy and trip data capture will be quicker and easier to use.
2. Artificially Intelligent Travel Suggestions: The user preferences, trip history, and location information can be processed using machine learning so that these data might be converted into personalized travel recommendations. The app could also be a proactive travel guide, as the system could suggest local attractions, restaurants, or events depending on the itinerary and time of the user.
3. Intelligent Itineration Optimization: The improvements of the future may contribute to the development of algorithms, which will analyse the travel schedules automatically taking into account the travel time between locations, the opening hours, and preferences

of the user. This would assist the travellers to make efficient and realistic plans.

4. Group Trip Collaboration The program can be expanded to allow the collaborative trip-planning in which two or more users can share a trip. The system would be appropriate in the situation of family and group travel due to features like shared itineraries, group expense splitting, and shared document access.
5. Advanced Expense Analytics The next version can be equipped with data visualization devices to compare the costs of travel over time. Charts and reports would possibly guide the user to comprehend their spending trends, compare and contrast trip budget, and make quality financial planning in future travelling.
6. Voice Assistant Interaction. Voice-based virtual assistants integration would enable the user to communicate with the app without using their hands. Through voice command, travellers would be able to view schedules and add expenses or check booking details, making the travelling process more convenient.
7. Wearable Device Support Some features like notifications and travel reminders could be extended to wearable products like smartwatches. It would enable the travellers to get alerts without always checking their phones, which increases accessibility and responsiveness.
8. Multi-Language Support In order to make the application worldwide, the next development might involve the use of several languages. This would assist the international travellers to use the system better.

These would make JourneyBox no longer just a travel organizer but a fully smart digital travel helper, one that can offer not only personalized recommendation, financial features, and better safety features.
